Network Markup Language Base Schema version 1

Status of This Document

Group Working Draft (GWD), candidate Recommendations Proposed (R-P).

Copyright Notice

Abstract

This document describes a set of normative schemas which allow the description of computer network topologies.

Contents

1 Introduction

This document describes the base schema of the Network Markup Language (NML). Section 2.1 defines the NML classes and their attributes and parameters. Section 2.2 describes the relations defined between NML classes.

An NML network description can be expressed in XML[XML], and RDF/XML[RDF-XML] syntax. Section A describes the XSD schema for the XML syntax. Section B describes the OWL 2 schema for the RDF/XML syntax.

These basic classes defined in this document may be extended, or sub-classed, to represent technology specific classes.

Section 5 provides example use cases. This section is informative. Only sections 2, 3, 4, and appendices A and B are normative and considered part of the recommendation.

1.1 Context

The Network Markup Language (NML) has been defined in the context of research and education networks to describe so-called hybrid network topologies. The NML is defined as an abstract and generic model, so it can be applied for other network topologies as well. See [GFD.165] for an detailed overview including prior work.

1.2 Scope

The Network Markup Language is designed to create a functional description of multi-layer networks and multi-domain networks. An example of a multi-layered network can be a virtualised network, but also using different technologies. The multi-domain network descriptions can include aggregated or abstracted network topologies. NML can not only describe a primarily static network topology, but also its potential capabilities and its configuration.

NML is aimed at logical connection-oriented network topologies, more precisely topologies where switching is performed on a label associated with a flow, such as a VLAN or wavelength. It can also be used to describe physical networks or packet-oriented networks, although the current base schema does not contain classes or properties to explicitly deal with signal degradation, or complex routing tables.

NML only attempts to describe the data plane of a computer network, not the control plane. It does contain extension mechanism to easily tie it with network provisioning standards and with network monitoring standards.

Finally, this document omits a definition for the terms *Network* or *capacity*. This has been

a conscious choice. The term *Network* has become so widely used for so many diverse meanings that it is impossible to create a definition that everyone can agree on, while still expressing something useful. See *Topology* for the concept of a network domain and a *Link* with multiple sources and sinks for the concept of a local area network. The term *capacity* is used by different technologies in such a different way (e.g. including or excluding the header and footer overhead) that it is better to let technology-specific extensions make an explicit definition.

1.3 Notational Conventions

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" are to be interpreted as described in [RFC 2119].

This schema defines classes, attributes, relations, parameters and logic. Objects are instances of classes, and the type of an object is a class.

Names of classes are capitalised and written in italics (e.g. the *Node* class). Names of relations are written in camel case and in italics (e.g. the *hasNode* relation).

2 NML Base Schema

The NML Base schema describes an information model for computer networks. This schema is kept intentionally general, with provisions to extend the schema to describe layer-specific information.

The schema consists of classes, attributes, relations, and parameters. Classes describe types of objects and are described in section 2.1. Relations describe the relations between classes and are described in section 2.2. Attributes describe properties of classes. Parameters, like attributes, are properties of classes, but may (subtly) change the logic. Attributes and parameters are described with their class description.

All classes, relations, attributes and parameters defined in this document have an identifier within the namespace `http://schemas.ogf.org/nml/2013/03/base#`.

2.1 Classes

Figure 1 shows an overview of all the classes in the NML schema in a UML class diagram. Each box defines the name of a class, a short description, and possible attributes with their

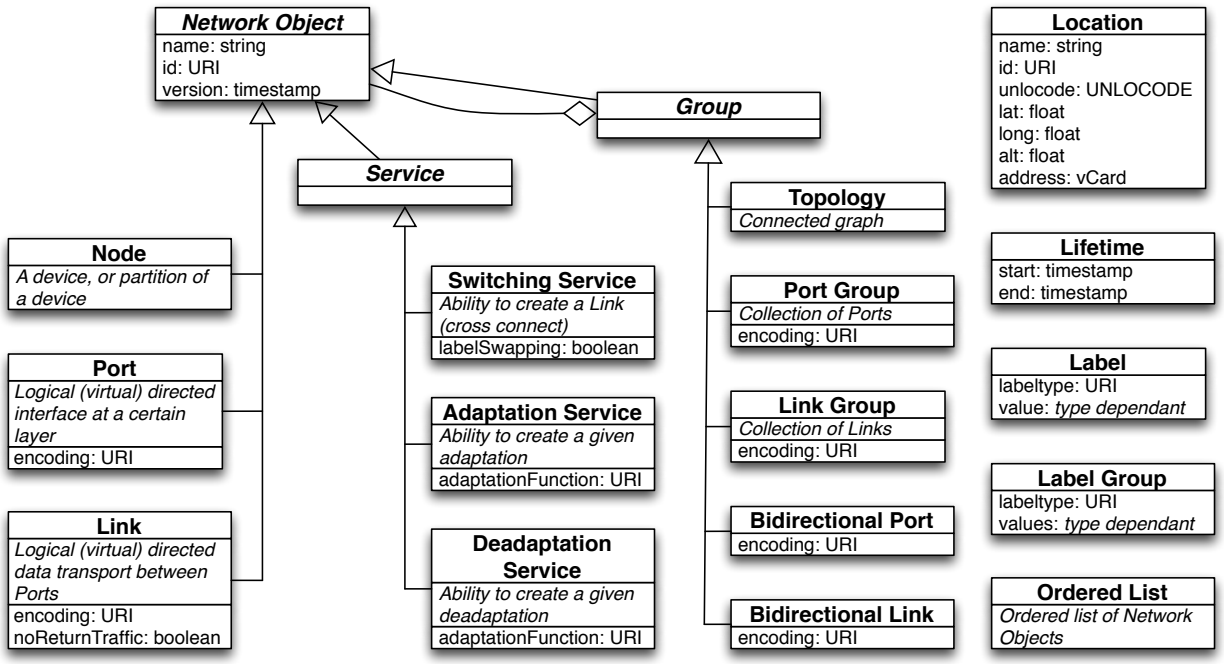

Figure 1: A UML class diagram of the classes in the NML schema and their hierarchy

value type. In the sections below we discuss each of the elements of the schema.

2.1.1 Network Object

The basic abstract class of the schema is the *Network Object*. Most classes inherit from it.

Network Object is an abstract class. It MUST NOT be instantiated directly.

A *Network Object* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *isAlias* to one or more *Network Object*s
- *locatedAt* to one *Location*

A *Network Object* may have the following attributes:

- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string
- *version* to assign a time stamp

The meaning of the *isAlias* relation is only defined for specific cases (between objects of the same concrete class), and SHOULD NOT be used between other objects.

The meaning of the *version* attribute is only defined for specific cases (for objects of the Topology class), and SHOULD NOT be used in other objects. Clients that receive a *version* attribute for a non-*Topology* object SHOULD ignore that attribute.

An *id* is a persistent, globally unique object identifier for the *Network Object*. The *id* SHOULD be used to refer to this object. Section 3 describes these identifiers in detail.

name is a human readable string. A name may be written in any language, but it is RECOMMENDED that names are chosen so that all users can easily distinguish between different names. Names are not globally unique, and two objects can have the same name. It is RECOMMENDED to use short, descriptive names. A name MUST NOT be used for anything other than display purposes. Normal Unicode recommendations apply: A name MUST NOT contain control or formatting codepoint, and it is RECOMMENDED to only use codepoints from the Basic Multilingual Plane (BMP).

version is a time stamp formatted as ISO 8601 calendar date, and MUST be a basic (compact) representation with UTC timezone (`YYYYMMDDThhmmssZ`) [ISO 8601]. The time stamp can be used to publish updates of a *Topology*. If a client receives multiple *Topology* descriptions, each with a different version time stamp, the version with the latest time stamp in the past or present MUST be considered the valid description. *Topology* descriptions with a time stamp

in the future MAY be discarded or cached until the denoted time. See also the *Lifetime* object to describe historic or future network changes.

The base *Network Object* is subclassed into the top-level topology components, that are sufficient to cover the description of networks. The classes in this schema that directly inherit from *Network Object* are:

- Node
- Port
- Link
- Service
- Group

These classes are described in more detail below.

2.1.2 Node

A *Node* is generally a device connected to, or part of, the network. A Node does not necessarily correspond to a physical machine. It MAY be a virtual device or a group of devices.

Node inherits from *Network Object*.

A *Node* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasInboundPort* to one or more *Port*s or *PortGroup*s
- *hasOutboundPort* to one or more *Port*s or *PortGroup*s
- *hasService* to one or more *Service*s of type *Switch*
- *implementedBy* to one or more *Node*s
- *isAlias* to one or more *Node*s
- *locatedAt* to one *Location*

A *Node* may have the following attributes:

- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

2.1.3 Port

A *Port* defines connectivity from a *Network Object* to the rest of the network. A *Port* object is unidirectional. A *Port* does not necessarily correspond to a physical interface. It represents a logical transport entity at a fixed place in the network.

Port inherits from *Network Object*.

A *Port* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasLabel* to one *Label*
- *hasService* to one or more *Service*s of type *Adaptation* or type *Deadaptation*
- *isAlias* to one or more *Port*s
- *isSink* to one or more *Link*s
- *isSource* to one or more *Link*s

A *Port* may have the following attributes:

- *encoding* to assign a data encoding identifier
- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

The *encoding* attribute defines the format of the data streaming through the Port. The identifier for the encoding MUST be a URI. Encoding URIs SHOULD be specified in a Grid Forum Documents (GFD).

2.1.4 Link

A *Link* object describes a unidirectional data transport from each of its sources to all of its sinks.

A source of a Link is a Network Object, e.g. a Port, that has a *isSource* relation to the Link. A sink of a Link is a Network Object, e.g. a Port, that has a *isSink* relation to the Link.

A *Link* object can refer to any link connection. A link segment and an end-to-end path are both described by a *Link* object. The composition of links into a path, and decomposition into link segments is described by the *isSerialCompoundLink* relation.

Link inherits from *Network Object*.

A *Link* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasLabel* to one *Label*
- *isAlias* to one or more *Link*s
- *isSerialCompoundLink* to one *Ordered List* of *Link*s

A *Link* may have the following attributes:

- *encoding* to assign a data encoding identifier
- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

A *Link* may have the following parameter:

- *noReturnTraffic*. A value of `true` changes the definition of *Link* to: data transport from each sources to all sinks, except that there is no data transport from a source to a sink if the source and sink are grouped together in a *BidirectionalPort* group. The default value of *noReturnTraffic* is `false`.

  An example of where this is used is in an Ethernet broadcast domain, where broadcast traffic is sent to all sinks, except the sink *Port*s associated with the sending source *Port*.

2.1.5 Service

Service describes a capability of the network. That is, it describes how the behavior can be changed dynamically.

Service is an abstract class. It MUST NOT be instantiated directly.

Service inherits from *Network Object*. A *Service* may have the same relations, attributes and parameters as a *Network Object*.

This schema defines three different services, the *SwitchingService* the *AdaptationService* and the *DeadaptationService*. These are described in more detail below.

2.1.6 Switching Service

A *SwitchingService* describes the ability to create new *Link*s from any of its inbound *Port*s to any of its outbound *Port*s.

SwitchingService inherits from *Service*.

A *SwitchingService* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasInboundPort* to one or more *Port*s or *PortGroup*s
- *hasOutboundPort* to one or more *Port*s or *PortGroup*s
- *isAlias* to one or more *Switching Service*s
- *providesLink* to one or more *Link*s or *LinkGroup*s.

A *SwitchingService* may have the following attributes:

- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

A *SwitchingService* may have the following parameter:

- *labelSwapping*. A value of `false` adds a restriction to the *SwitchingService*: it is only able to create cross connects from an inbound *Port* to an outbound *Port* if the *Label* of the connected *Port*s has the same value. The default value is `false`.

The *providesLink* relation points to *Link*s which describe the currently configured cross connects in a *SwitchingService*.

2.1.7 Adaptation Service

An *AdaptationService* describes the capability that data from one or more *Port*s can be embedded in the data encoding of one other *Port*. This is commonly referred to as the embedding of client layer (higher network layer) ports in a server layer (lower network layer) port. The *AdaptationService* describes a multiplexing adaptation function, meaning that different channels (the client layer ports) can be embedded in a single data stream (the server layer port). For example multiplexing several VLANs over a single trunk port.

Like *Port* and *Link*, *AdaptationService* describes a unidirectional transport function. For the inverse transport function, see *DeadaptationService*.

AdaptationService inherits from *Service*.

An *AdaptationService* may have the following relations:

- *canProvidePort* to one or more *Port*s or *PortGroup*s (this describes a capability)
- *existsDuring* to one or more *Lifetime*s

- *isAlias* to one or more *AdaptationService*s
- *providesPort* to one or more *Port*s or *PortGroup*s (this describes a configuration)

An *AdaptationService* may have the following attributes:

- *adaptationFunction* to assign an adaptation technology identifier
- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

DeadaptationService is an inverse of *AdaptationService*. This should not be confused with an inverse multiplexing adaptation function. An inverse multiplexing adaptation function embeds a single data stream in multiple underlying data streams. To describes such a network, the *parallelCompound* relation can be used, which is a future extension relation, described in a separate document [Dijkstra13].

2.1.8 De-adaptation Service

A *DeadaptationService* describes the capability that data of one or more ports can be extracted from the data encoding of one other port. This is commonly referred to as the extraction of client layer (higher network layer) ports from the server layer (lower network layer) port. The *DeadaptationService* describes a demultiplexing adaptation function, meaning that different channels (the client layer ports) can be extracted from a single data stream (the server layer port). For example demultiplexing several VLANs from a single trunk port.

Like *Port* and *Link*, *AdaptationService* describes a unidirectional transport function. For the inverse transport function, see *AdaptationService*.

DeadaptationService inherits from *Service*.

A *DeadaptationService* may have the following relations:

- *canProvidePort* to one or more *Port*s or *PortGroup*s
- *existsDuring* to one or more *Lifetime*s
- *isAlias* to one or more *DeadaptationService*s
- *providesPort* to one or more *Port*s or *PortGroup*s

A *DeadaptationService* may have the following attributes:

- *adaptationFunction* to assign a adaptation technology identifier
- *id* to assign a persistent globally unique URI

- *name* to assign a human readable string

2.1.9 Group

A *Group* describes a collections of objects. Any object can be part of a group, including another *Group*. An object can also be part of multiple *Group*s.

Group is an abstract class. It MUST NOT be instantiated directly.

Group inherits from *Network Object*. A *Group* may have the same relations, attributes and parameters as a *Network Object*.

This schema defines five different *Group*s:

- Topology
- Port Group
- Link Group
- Bidirectional Port
- Bidirectional Link

These classes are described in more detail below.

2.1.10 Topology

A *Topology*[1] is a set of connected *Network Object*s. *connected* means that there is, or it is possible to create, a data transport between any two Network Objects in the same Topology, provided that there are no policy, availability or technical restrictions.

A *Topology* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasNode* to one or more *Node*s
- *hasInboundPort* to one or more *Port*s or *PortGroup*s
- *hasOutboundPort* to one or more *Port*s or *PortGroup*s
- *hasService* to one or more *Service* of type *Switch*
- *hasTopology* to one or more *Topology*s

[1] At first this was called a Network, then Graph Network. The term Topology was suggested to avoid the confusion surrounding the overloaded term Network.

- *isAlias* to one or more *Topology*s
- *locatedAt* to one *Location*

A *Topology* may have the following attributes:

- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string
- *version* to assign a serial number

The *version* attribute is described at the *Network Object*.

2.1.11 Port Group

A *PortGroup* is an unordered set of *Port*s.

A *PortGroup* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasLabelGroup* to one *LabelGroup*
- *hasPort* to one or more *Port*s or *PortGroups*
- *isAlias* to one or more *PortGroup*s
- *isSink* to one or more *LinkGroup*s
- *isSource* to one or more *LinkGroup*s

A *PortGroup* may have the following attributes:

- *encoding* to assign a data encoding identifier
- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

2.1.12 Link Group

A *LinkGroup* is an unordered set of *Link*s.

A *LinkGroup* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasLabelGroup* to one *LabelGroup*

- *hasLink* to one or more *Link*s or *LinkGroup*s
- *isAlias* to one or more *LinkGroup*s
- *isSerialCompoundLink* to *Ordered List* of *LinkGroup*s

A *LinkGroup* may have the following attributes:

- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

2.1.13 Bidirectional Port

A *BidirectionalPort* is a group of two (unidirectional) *Port*s or *PortGroup*s together forming a bidirectional representation of a physical or virtual port. See Figure 2 for an example of a *BidirectionalPort* and its associated *Port*s.

A *BidirectionalPort* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasPort* to exactly two *Port*s or two *PortGroup*s

A *BidirectionalPort* may have the following attributes:

- *encoding* to assign a data encoding identifier
- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

There is explicitly no direct relation between a *BidirectionalPort* and a *BidirectionalLink*, since NML is a unidirectional model.

2.1.14 Bidirectional Link

A *BidirectionalLink* is a group of two (unidirectional) *Link*s or *LinkGroup*s together forming a bidirectional link. See Figure 2 for an example of a *BidirectionalLink* and its associated *Link*s.

A *BidirectionalLink* may have the following relations:

- *existsDuring* to one or more *Lifetime*s
- *hasLink* to exactly two *Link*s or two *LinkGroup*s

A *BidirectionalLink* may have the following attributes:

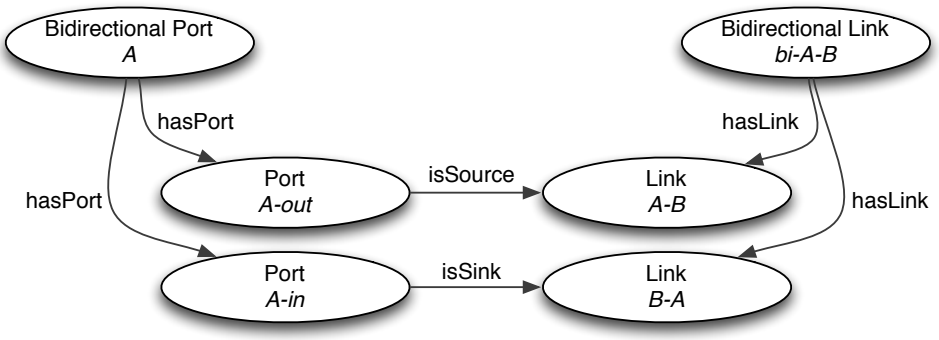

Figure 2: An abstract example of *BidirectionalPort* and *BidirectionalLink*

- *encoding* to assign a data encoding identifier
- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string

There is explicitly no direct relation between a *BidirectionalPort* and a *BidirectionalLink*, since NML is a unidirectional model.

2.1.15 Location

A *Location* is a reference to a geographical location or area. A *Location* object can be related to other *Network Object*s to describe that these are located there. This can be relevant for network measurements, visualisations, et cetera.

A *Location* may have the following attributes:

- *id* to assign a persistent globally unique URI
- *name* to assign a human readable string
- *long* is the longitude in WGS84 coordinate system (in decimal degrees) [WGS84]
- *lat* is the latitude in WGS84 coordinate system (in decimal degrees)
- *alt* is the altitude in WGS84 coordinate system (in decimal meters)
- *unlocode* is the UN/LOCODE location identifier [UNLOCODE]
- *address* is a vCard ADR (address) property. The exact syntax of the address property is not specified, to allow other (e.g. XML or RDF) representations of the string-based format specified in [RFC 6350].

2.1.16 Lifetime

A *Lifetime* is an interval between which the object is said to be active. This can be used to track changes in a network, reflect dynamic operations, to help debug problems, et cetera.

A *Lifetime* MAY have the following attributes:

- *start* is the start time and date formatted as ISO 8601 calendar date, and SHOULD be a basic (compact) representation with UTC timezone (*YYYYMMDD*T*hhmmss*Z) [ISO 8601]
- *end* is the end time and date formatted as ISO 8601 calendar date, and SHOULD be a basic (compact) representation with UTC timezone (*YYYYMMDD*T*hhmmss*Z)

Objects with multiple lifetimes mean that the lifetime of the object is the union of all lifetimes (as opposed to a intersection).

If a Network Object has no associated *Lifetime* objects, or the start or end attribute of a Lifetime object is missing, the default lifetime may be assumed to start on or before the time specified in the version attribute of the most specific Topology object that contains this Network Object. The end of that assumed lifetime is indefinite, until a Topology object with a higher version number is published.

If a Network Object has no associated Lifetime objects, and the Topology object does not have a version attribute, than the lifetime of the Network Object is undefined.

2.1.17 Label

A *Label* is the technology-specific value that distinguishes a single data stream (a channel) embedded in a larger data stream. The *Label* can be a resource label (with one value). In a future extension it may be a pair of source and destination labels (with two values) [G.800]. Examples of resource labels are a VLAN number, wavelength, et cetera.

A *Label* may have the following attributes:

- *type* to refer to a technology-specific labelset, e.g. a URI for VLANs
- *value* is one specific value taken from the labelset, e.g. a VLAN number

Technology extensions of NML may define additional attributes. Label type URIs SHOULD be specified in a Grid Forum Documents (GFD), which SHOULD also define possible values.

This version of NML only deals with resource labels. The use of source and destination labels is a future extension [Dijkstra13].

2.1.18 Label Group

A *LabelGroup* is an unordered set of *Label*s.

A *LabelGroup* may have the following attributes:

- *type* to refer to a technology-specific labelset
- *values* is a set of specific values taken from the labelset

Technology extensions of NML may define additional attributes.

2.1.19 Ordered List

An *Ordered List* is an ordered list of *Network Object*s. These are used for the *isSerialCompoundLink* relation to an ordered list of *Link*s to describe a path through the network.

The representation of an *Ordered List* depends on the syntax, and is defined in section 4.4.

2.1.20 List Item

A *ListItem* is a syntactical construct which may be used by syntaxes to construct a *Ordered List*. The exact usage depends on the syntax.

2.2 Relations

*Relation*s describe how different *Network Object*s relate to each other, typically to form a network topology description. The relations have been listed above, and are defined here (in alphabetical order). In principle a *Relation* can go from any object to any other object.

The list below makes a distinction between *allowed* and *defined* relations. An *allowed* relation means it is valid NML. A *defined* relation means that it has a specific meaning, as described here.

A relation which is NOT *allowed* MUST be rejected by a client, and the sender SHOULD be notified with an error. A relation which is *allowed*, but (yet) *undefined* SHOULD be ignored by a client (either silently, or with a warning to the sender). This distinction allows future extension of NML, while retaining limited backward compatibility.

The *existsDuring*, *hasLabel*, *hasLabelGroup*, *hasLink*, *hasNode*, *hasPort*, *hasService*, *hasTopology*, *locatedAt*, *providesLink*, and *providesPort* are defined as *implicit* relations. All other relations are *explicit*. The distinction between implicit and explicit relations may be used by some syntaxes to allow a more compact network description.

2.2.1 canProvidePort

canProvidePort is used to relate an *AdaptationService* or *DeadaptationService* to one or more *Port*s or *PortGroup*s to define that these can be created by that *AdaptationService* or *DeadaptationService*.

Allowed relations are:

- *Service* —(canProvidePort ▸, * to *)— *Port*
- *Service* —(canProvidePort ▸, * to *)— *PortGroup*

Defined relations are:

- *AdaptationService* —(canProvidePort ▸, * to *)— *Port*
- *AdaptationService* —(canProvidePort ▸, * to *)— *PortGroup*
- *DeadaptationService* —(canProvidePort ▸, * to *)— *Port*
- *DeadaptationService* —(canProvidePort ▸, * to *)— *PortGroup*

2.2.2 existsDuring

existsDuring relates one *Network Object* object to zero or more *LifeTime* objects. This defines the existence of the object at a certain time.

Network Object —(existsDuring ▸, 1 to *)— *LifeTime*

Objects with multiple lifetimes mean that the lifetime of the object is the union of all lifetimes (as opposed to a intersection).

If a Network Object has no associated Lifetime objects, or the start or end attribute of a Lifetime object is missing, the default lifetime may be assumed to start on or before the time specified in the version attribute of the most specific Topology object that contains this Network Object, and the end on or later than the version attribute of the next published Topology object.

If a Network Object has no associated Lifetime objects, and the Topology object does not have a version attribute, than the lifetime of the Network Object is undefined.

2.2.3 hasInboundPort

hasInboundPort defines the relation between a *Node*, a *SwitchingService* or a *Topology* and their respective *Port*s or *PortGroup*s

Allowed relations are:

- *Network Object* —(*) hasInboundPort ▸ (*)— *Port*
- *Network Object* —(*) hasInboundPort ▸ (*)— *PortGroup*

Defined relations are:

- *Node* —(*) hasInboundPort ▸ (*)— *Port*
- *Node* —(*) hasInboundPort ▸ (*)— *PortGroup*
- *SwitchingService* —(*) hasInboundPort ▸ (*)— *Port*
- *SwitchingService* —(*) hasInboundPort ▸ (*)— *PortGroup*
- *Topology* —(*) hasInboundPort ▸ (*)— *Port*
- *Topology* —(*) hasInboundPort ▸ (*)— *PortGroup*

This defines that the related *Network Object* has an inbound *Port* or *PortGroup* object. The direction of the *Port* object is relative to the *Network Object* the *Port* is attached to, so in this case the traffic flows towards that *Network Object* (similarly for the *PortGroup*). This *Port* would then be related to a *Link* object using the *isSink* relation (or a*PortGroup* and *LinkGroup* respectively).

A *Network Object* with a *hasInboundPort* relation pointing to a *PortGroup* has the same meaning as defining a *hasInboundPort* relation pointing to every *Port* in that *PortGroup* (as defined by a *hasPort* relation between the *PortGroup* and *Port*).

2.2.4 hasLabel

hasLabel assigns one *Label* to a *Port* or *Link*

Allowed relations are:

- *Port* —(1) hasLabel ▸ (*)— *Label*
- *Link* —(1) hasLabel ▸ (*)— *Label*

The *Label* assigned to a *Port* or *Link* is the technology label that identifies the traffic through this *Port* or *Link* (including in *Link*s provided by a *SwitchingMatrix*).

A *Label* is used to distinguish a *Port* in a *PortGroup*, or distinguish a *Link* in a *LinkGroup*.

The meaning of *hasLabel* is only *defined* for a cardinality of 0 or 1.

2.2.5 hasLabelGroup

hasLabelGroup assigns one *LabelGroup* to a *PortGroup* or *LinkGroup*

Allowed relations are:

- *PortGroup* —(hasLabelGroup ▸, 1 : *)— *LabelGroup*
- *LinkGroup* —(hasLabelGroup ▸, 1 : *)— *LabelGroup*

The *LabelGroup* assigned to this *PortGroup* or *LinkGroup* defines the *Label*s associated with the *Port*s member of that group. There MUST be a one-to-one correspondence between the *LabelGroup* and the *PortGroup*.

The meaning of *hasLabelGroup* is only defined for a cardinality of 0 or 1.

2.2.6 hasLink

hasLink is used for:

- *BidirectionalLink* to relate exactly two *Link*s or two *LinkGroup*s
- *LinkGroup* to one or more *Link*s or *LinkGroup*s to define membership of that group

Allowed relations are:

- *Group* —(hasLink ▸, * : *)— *Link*
- *Group* —(hasLink ▸, * : *)— *LinkGroup*

Defined relations are:

- *LinkGroup* —(hasLink ▸, * : *)— *Link*
- *LinkGroup* —(hasLink ▸, * : *)— *LinkGroup*
- *BidirectionalLink* —(hasLink ▸, * : 2)— *Link*
- *BidirectionalLink* —(hasLink ▸, * : 2)— *LinkGroup*

The *hasLink* relationships for a *BidirectionalLink* point to the two unidirectional *Link*s that together form a bidirectional connection between its respective associated *Node*s.

The *hasLink* relationships for a *LinkGroup* define the membership of the *Link*s in that *LinkGroup*.

2.2.7 hasNode

hasNode relates a *Topology* to a *Node*, meaning that a *Node* is part of a *Topology*

Allowed relations are:

- *Network Object* —(hasNode ▸, * : *)— *Node*

Defined relations are:

- *Topology* —(hasNode ▸, * : *)— *Node*

2.2.8 hasOutboundPort

hasOutboundPort relates either a *Node*, *SwitchingService* or a *Topology* to one or more *Port*s or *PortGroup*s.

Allowed relations are:

- *Network Object* —(hasOutboundPort ▸, * : *)— *Port*
- *Network Object* —(hasOutboundPort ▸, * : *)— *PortGroup*

Defined relations are:

- *Node* —(hasOutboundPort ▸, * : *)— *Port*
- *Node* —(hasOutboundPort ▸, * : *)— *PortGroup*
- *SwitchingService* —(hasOutboundPort ▸, * : *)— *Port*
- *SwitchingService* —(hasOutboundPort ▸, * : *)— *PortGroup*
- *Topology* —(hasOutboundPort ▸, * : *)— *Port*
- *Topology* —(hasOutboundPort ▸, * : *)— *PortGroup*

This defines that the related *Network Object* has an outbound *Port* or *PortGroup* object. The direction of the *Port* object is relative to the *Network Object* the *Port* is attached to, so

in this case the traffic flows away from that *Network Object* (similarly for the *PortGroup*). This *Port* would then be related to a *Link* object using the *isSource* relation (or a*PortGroup* and *LinkGroup* respectively).

A *Network Object* with a *hasOutboundPort* relation pointing to a *PortGroup* has the same meaning as defining a *hasOutboundPort* relation pointing to every *Port* in that *PortGroup* (as defined by a *hasPort* relation between the *PortGroup* and *Port*).

2.2.9 hasPort

hasPort is used for:

- *BidirectionalPort* to relate exactly two *Port*s or two *PortGroup*s
- *PortGroup* to one or more *Port*s or *PortGroup*s

Allowed relations are:

- *Group* —(hasPort ▸, * — *)— *Port*
- *Group* —(hasPort ▸, * — *)— *PortGroup*

Defined relations are:

- *PortGroup* —(hasPort ▸, * — *)— *Port*
- *PortGroup* —(hasPort ▸, * — *)— *PortGroup*
- *BidirectionalPort* —(hasPort ▸, * — 2)— *Port*
- *BidirectionalPort* —(hasPort ▸, * — 2)— *PortGroup*

The *hasPort* relationships for a *BidirectionalPort* point to the two unidirectional *Port*s that together form a bidirectional port for the associated *Node*.

The *hasPort* relationships for a *PortGroup* define the membership of the *Port*s in that *PortGroup*.

2.2.10 hasService

hasService relates a *Network Object* to a *Service*. This schema only defines the meaning of:

- *Port* to *AdaptationService*, relating one server-layer *Port* to an adaptation function.
- *Port* to *DeadaptationService*, relating one server-layer *Port* to a deadaptation function.

- *Node* or *Topology* to *SwitchingService*, describing a switching capability of that *Node* or *Topology*.

Allowed relations are:

- *Network Object* —(hasService ▸, * : *)— *Service*

Defined relations are:

- *Port* —(hasService ▸, 1 : *)— *AdaptationService*
- *Port* —(hasService ▸, 1 : *)— *DeadaptationService*
- *Node* —(hasService ▸, * : *)— *SwitchingService*
- *Topology* —(hasService ▸, * : *)— *SwitchingService*

2.2.11 hasTopology

hasTopology defines a relation between one *Topology* to one or more *Topology*s for aggregation purposes.

Allowed relations are:

- *Network Object* —(hasTopology ▸, * : *)— *Topology*

Defined relations are:

- *Topology* —(hasTopology ▸, * : *)— *Topology*

2.2.12 implementedBy

implementedBy relates a *Node* to one or more *Node*s to describe virtualization.

Allowed relations are:

- *Network Object* —(implementedBy ▸, * : *)— *Network Object*

Defined relations are:

- *Node* —(implementedBy ▸, * : *)— *Node*

2.2.13 isAlias

isAlias is a relation from a *Network Object* to a *Network Object* to describe that one can be used as the alias of another.

Allowed relations are:

- *Network Object* —(isAlias ▸, * : *)— *Network Object*

The relation is only defined if the type of both objects is the same (e.g. a Node can be related to another Node, but if it is related to a Topology using the *isAlias* relation, that relation is *undefined*.)

2.2.14 isSerialCompoundLink

isSerialCompoundLink is used to define that a *Link* or *LinkGroup* represents an ordered *List* of *Link*s or *LinkGroup*s. This must include cross-connects.

The following relation is allowed and defined:

- *Link* —(isSerialCompoundLink ▸, 1 : *)— [*1.* *Link*; *2.* *Link*; …; *n.* *Link*]

The following relation is allowed, but undefined:

- *LinkGroup* —(isSerialCompoundLink ▸, * : *)— [*1.* *LinkGroup*; *2.* *LinkGroup*; …; *n.* *LinkGroup*]

2.2.15 isSink

isSink relates a *Port* to one *Link* to define the outgoing traffic port, and similarly for *PortGroup* and *LinkGroup*.

Allowed relations are:

- *Network Object* —(isSink ▸, * : *)— *Link*
- *Network Object* —(isSink ▸, * : *)— *LinkGroup*

Defined relations are:

- *Port* —(isSink ▸, * : *)— *Link*
- *PortGroup* —(isSink ▸, * : *)— *LinkGroup*

isSink between a *PortGroups* and a *LinkGroup* is *defined* only if the *PortGroup* and *LinkGroup* in question have the exact same *LabelGroup*.

2.2.16 isSource

isSource relates a *Port* to one *Link* to define its incoming traffic port, and similarly for *PortGroup* and *LinkGroup*.

Allowed relations are:

- *Network Object* —(isSource ▸, * : *)— *Link*
- *Network Object* —(isSource ▸, * : *)— *LinkGroup*

Defined relations are:

- *Port* —(isSource ▸, * : *)— *Link*
- *PortGroup* —(isSource ▸, * : *)— *LinkGroup*

isSource between a *PortGroups* and a *LinkGroup* is *defined* only if the *PortGroup* and *LinkGroup* in question have the exact same *LabelGroup*.

2.2.17 item

A *item* relation is a syntactical construct which may be used by syntaxes to construct a *Ordered List*. The exact usage depends on the syntax.

2.2.18 locatedAt

locatedAt relates a *Network Object* to one *Location* to describe that a *Network Object* is located at that *Location*.

- *Network Object* —(locatedAt ▸, * : *)— *Location*

2.2.19 next

next relation is a syntactical construct which may be used by syntaxes to construct a *Ordered List*. The exact usage depends on the syntax.

2.2.20 providesLink

providesLink is used to relate a *SwitchingService* to one or more *Link*s or *LinkGroup*s to define that these have been created by that *SwitchingService*.

Allowed relations are:

- *Service* —providesLink ▸ (*:*)— *Link*
- *Service* —providesLink ▸ (*:*)— *LinkGroup*

Defined relations are:

- *SwitchingService* —providesLink ▸ (1:*)— *Link*
- *SwitchingService* —providesLink ▸ (1:*)— *LinkGroup*

2.2.21 providesPort

providesPort is used to relate an *AdaptationService* or *DeadaptationService* to one or more *Port*s or *PortGroup*s to define that these have been created by that *AdaptationService* or *DeadaptationService*.

Allowed relations are:

- *Service* —providesPort ▸ (*:*)— *Port*
- *Service* —providesPort ▸ (*:*)— *PortGroup*

Defined relations are:

- *AdaptationService* —providesPort ▸ (1:*)— *Port*
- *AdaptationService* —providesPort ▸ (1:*)— *PortGroup*
- *DeadaptationService* —providesPort ▸ (1:*)— *Port*
- *DeadaptationService* —providesPort ▸ (1:*)— *PortGroup*

2.3 Attributes

Attributes are properties of an object. The following attributes have been defined in section 2.1.

Attribute	**Class (section)**
adaptationFunction	AdaptationService (2.1.7), DeadaptationService (2.1.8)
address	Location (2.1.15)
alt	Location (2.1.15)
encoding	Port (2.1.3), Link (2.1.4), PortGroup (2.1.11), LinkGroup (2.1.12), BidirectionalPort (2.1.14), BidirectionalLink (2.1.14),
end	LifeTime (2.1.16)
id	NetworkObject (2.1.1), Location (2.1.15)
labeltype	Label (2.1.17), LabelGroup (2.1.18)
lat	Location (2.1.15)
long	Location (2.1.15)
name	NetworkObject, Location (2.1.15)
start	LifeTime (2.1.16)
unlocode	Location (2.1.15)
value	Label (2.1.17)
values	LabelGroup (2.1.18)
version	NetworkObject (2.1.1)

2.4 Parameters

Parameters are properties of an object. Parameters, like attributes, are properties of objects, but may (subtly) change the logic of the object. The following parameters have been defined in section 2.1.

Parameter	**Class (section)**
labelSwapping	SwitchingService (2.1.6)
noReturnTraffic	Link (2.1.4)

3 Identifiers

3.1 Schema Identifier

The namespace for the schema defined in document is `http://schemas.ogf.org/nml/base/2013/03#`. (TODO: Update to right date after publication)

All classes, relations, parameters and attributes defined in this document reside in this namespace. For example, the Link class is identified by `http://schemas.ogf.org/nml/2013/03/base#Link`

3.2 Instance Identifiers

Section 2.1.1 requires that instances of Network Objects SHOULD have an *id* attribute, which MUST be a unique URI.

Implementations that receive a network topology description MUST be prepared to accept any valid URI as an identifier.

Implementations that publish a network topology description instance identifiers MAY adhere to the syntax of Global Network Identifiers as defined in [URN-OGF-NETWORK], which ensures global uniqueness and easy recognition as Network Object instances.

Two different Network Objects instances MUST have two different identifiers.

Once an identifier is assigned to a resource, it MUST NOT be re-assigned to another resource.

A URI MAY be interpreted as an International Resource Identifier (IRI) for display purposes, but URIs from external source domains MUST NOT be IRI-normalised before transmitting to others.

3.2.1 Lexical Equivalence

Two identifier are lexical equivalent if they are binary equivalent after case folding[2] [Unicode].

Other interpretation (such as percent-decoding or Punycode decoding [RFC 3492]) MUST NOT take place.

For the purpose of equivalence comparison, any possible fragment part or query part of the URI is considered part of the URI.

For example the following identifiers are equivalent:

[2] *Case folding* is primarily used for caseless comparison of text. *Case mapping* is used for display purposes.

```
1 - urn:ogf:network:example.net:2013:local_string_1234
2 - URN:OGF:network:EXAMPLE.NET:2013:Local_String_1234
```

While the following identifiers are not equivalent (in this case, the percentage encoding even makes URI #3 an invalid Global Network Identifier.):

```
1 - urn:ogf:network:example.net:2013:local_string_1234
3 - urn:ogf:network:example.net:2013:local%5Fstring%5F1234
```

3.2.2 Further Restrictions

An assigning organisation MUST NOT assign Network Object Identifier longer than 255 characters in length.

Parsers MUST be prepared to accept identifiers of up to 255 characters in length.

A Parser SHOULD verify if an identifier adheres to the general URI syntax rules, as specified in RFC 3986 [RFC 3986].

Parsers SHOULD reject identifiers which do not adhere to the specified rules. A parser encountering an invalid identifier SHOULD reply with an error code that includes the malformed identifier, but MAY accept the rest of the message, after purging all references to the Network Object with the malformed identifier.

3.2.3 Interpreting Identifiers

A Network Object identifier MUST be treated as a opaque string, only used to uniquely identify a Network Object. The local-part of a Global Network Identifier MAY have certain meaning to it's assigning organisation, but MUST NOT be interpreted by any other organisation.

3.2.4 Network Object Attribute Change

A Network Object may change during its lifetime. If these changes are so drastic that the assigning organisation considers it a completely new Network Object, the assigning organisation should be assigned a new identifier. In this case, other organisations MUST treat this object as completely new Network Resource.

If the assigning organisation considers the changes are small, it MUST retain the same identifier for the Network Object, and use some mechanism to signal it's peers of the changes in the attributes of the Network Object. An appropriate mechanism is to send a new description of the Topology or the Network Object with an updated *version* attribute.

3.3 Unnamed Objects

Network Objects that do not have a regular URI as id attribute, may have either:

- Have no id attribute. These are so-called *unnamed* network objects.
- Have an id attribute which is a fragment identifier only, thus an URI starting with a crosshatch (#) character. These are so-called *ad-hoc named* network objects.

A *unnamed* network object can not be referenced. A network objects generally SHOULD NOT be unnamed, since there is no possibility for an external party to refer to the object.

A *ad-hoc named* network object can only be referenced from within the same topology description. *ad-hoc id*s must be considered a syntactical construct, not as a persistent identifier. The MUST NOT be referred to from another scope or another topology description. *ad-hoc id*s SHOULD NOT be stored. If a two peers exchange topology messages, it is perfectly valid to change the ad-hoc id in each message (since they are only valid within scope of that message anyway).

A possible reason to use unnamed or ad-hoc named network objects it to make a statement such as *"Port A and Port B are grouped in a BidirectionalPort"* without actually assigning an identifier to this BidirectionalPort.

4 Syntax

The Network Markup Language has two different normative syntaxes. The syntaxes are in regular XML defined using an XML Schema (XSD), and another in OWL RDF/XML syntax, defined in an OWL schema. The OWL syntax is aimed at Semantic Web-oriented applications, the XML syntax is suitable for any application. These syntaxes are defined in Appendices A and B respectively. These syntaxes follow the model as defined in section 2, should there be any inconsistencies between the syntaxes, the definitions in section 2 take precedence over the syntaxes.

4.1 XML Syntax

An NML object is represented as an XML element. For example:

```
1 <nml:BidirectionalLink />
```

An NML attribute or parameter is represented as either an XML attribute, XML child element or text value of the XML element. The table list the mapping for the attributes and parameters defined in this document:

XML representation	**Attribute**	**Child element**	**Text of element**
NML attribute or parameter	id	name	value
	adaptationFunction	address	values
	encoding	lat	
	labeltype	long	
	version	alt	
	noReturnTraffic	unlocode	
	labelSwapping	start	
		end	

For example:

```
1 <nml:Port id="urn:ogf:network:example.net:2012:port_X.1501:in">
2   <nml:name>VLAN 1501 at Port X (in)</nml:name>
3   <nml:Label labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">1501</nml:Label>
4 </nml:Port>
```

Explicit relation are represented as a `<nml:Relation>` XML element, with the domain as the parent element, and the range as the child element. Implicit relations are not given: the range object is represented as an XML child element of the domain. Below is an example of an explicit relation:

```
<nml:Port id="urn:ogf:network:example.net:2012:port_X:out">
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#isSource">
    <nml:Link id="urn:ogf:network:example.net:2012:linkA:XY"/>
  </nml:Relation>
</nml:Port>
```

And this is an example of an implicit relation:

```
<nml:Topology id="urn:ogf:network:example.net:2012:Example_Network">
  <nml:Node id="urn:ogf:network:example.net:2012:example_node"/>
</nml:Port>
```

4.2 OWL RDF/XML Syntax

An NML object is represented as an RDF subject.

An NML attribute or parameter is represented as a predicate.

For example:

```
<nml:Port rdf:about="urn:ogf:network:example.net:2012:port_X.1501:in">
  <nml:name>VLAN 1501 at Port X (in)</nml:name>
  <nml:hasLabel>
    <nml:Label>
      <nml:labeltype rdf:resource="http://schemas.ogf.org/nml/2013/03/ethernet#vlan"/>
      <nml:value>1501</nml:value>
    </nml:Label>
  </nml:hasLabel>
</nml:Port>
```

Relations are represented as an RDF triplet, with the full URI of the attribute or parameter. For example:

```
<nml:Port rdf:about="urn:ogf:network:example.net:2012:port_X:out">
   <nml:isSource rdf:resource="urn:ogf:network:example.net:2012:linkA:XY"/>
</nml:Port>
```

4.3 Combining Object Descriptions

A given object may have multiple attributes and relations. These attributes and relations may be described in different places in a syntax. It is up to the parser to combine all attributes and relations.

NML currently does not have a mechanism to check if a given description of an object is *complete*. Thus, it does not distinguish between a full description of an object or merely a pointer to an object.

Parsers should be aware that the NML descriptions do not provide any guarantee regarding the integrity nor the authenticity of the description. Parsers are advised to use external mechanism to avoid that an erroneous description of an object in one (possibly malicious) topology description pollutes a correct description of the same object in another topology description.

4.4 Ordered Lists

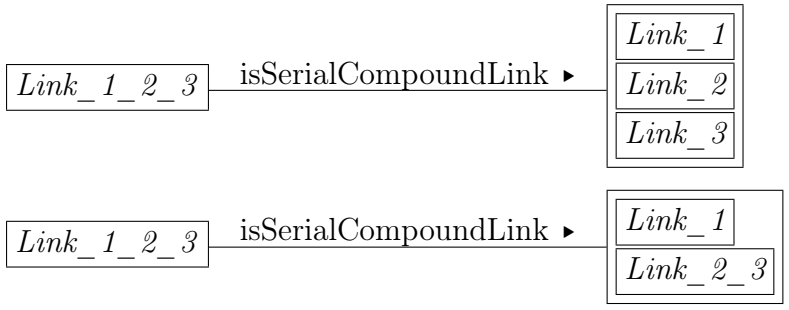
The range of an *isSerialCompoundLink* relation is an *Ordered List*.

Neither XML nor OWL uses the *Ordered List* directly in the syntax, and have a different way of constructing ordered lists. XML lists values with additional *next* relations, while OWL uses a *ListItem* class, and the *item* and *next* relations.

A *ListItem* behaves as a class, while *item* and *next* behave like relations, with the exception that these classes and relations are local in scope.

This means that these relations are only valid within the scope of a given *Ordered List*, but may not be valid in scope of a different *Ordered List*. It also means that any identifier given to these classes may change when the objects are codified in a syntax.

For example, consider the following two decompositions of *Link* `Link_1_2_3` into shorter *Links*:



In the first *Ordered List*, there is a *next* relation from `Link_1` to `Link_2`, while in the second Ordered List, the *next* relation is from `Link_1` to `Link_2_3`.

In XML an *Ordered List* can be constructed by using all objects in the list as child elements, and using a *next* relation between consecutive objects in the list to denote ordering.

In OWL an *Ordered List* can be constructed by creating as many *ListItem* objects as there

are items in the list. Each *ListItem* object is correlated with the actual list item using the *item* relation, while using a *next* relation to point to the following *ListItem*. A predicate points to the first *ListItem* in the *Ordered List* to point to the whole list, which is chained using the *next* relation.

See also the *isSerialCompoundLink* examples in the example section.

5 Examples

5.1 Examples in XML

The following snippets represent NML structures in the XML format.

- *Topology* (section 2.1.10)

```
<nml:Topology xmlns:nml="http://schemas.ogf.org/nml/2013/03/base#"
              id="urn:ogf:network:example.net:2012:org"
              version="20120814">

  <!-- ... -->

</nml:Topology>
```

- *Node* (section 2.1.2)

```
<nml:Node id="urn:ogf:network:example.net:2012:nodeA">
  <nml:name>Node_A</nml:name>
  <nml:Location id="urn:ogf:network:example.net:2012:redcity"/>
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#hasOutboundPort">
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_X:out"/>
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_Y:out"/>
  </nml:Relation>
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#hasInboundPort">
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_X:in"/>
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_Y:in"/>
  </nml:Relation>
</nml:Node>
```

- *Ports*
  - *UnidirectionalPort* (section 2.1.3)

```
<nml:Port id="urn:ogf:network:example.net:2012:port_X:out">
  <nml:Label labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">1501</nml:Label>
</nml:Port>
```

  - *BidirectionalPort* (section 2.1.13)

```
<nml:BidirectionalPort id="urn:ogf:network:example.net:2012:port_X">
  <nml:name>X</nml:name>
  <nml:Port id="urn:ogf:network:example.net:2012:port_X:out"/>
  <nml:Port id="urn:ogf:network:example.net:2012:port_X:in"/>
</nml:BidirectionalPort>
```

- *PortGroup* (section 2.1.11)

```
<nml:PortGroup id="urn:ogf:network:example.net:2012:portgroup_X:out">
  <nml:LabelGroup labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">
    1780−1783
  </nml:LabelGroup>
</nml:PortGroup>
```

- *Links*
  - *UnidirectionalLink* (section 2.1.4)

```
<nml:Link id="urn:ogf:network:example.net:2012:linkA:XY"/>

<nml:Port id="urn:ogf:network:example.net:2012:port_X:out">
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#isSource">
    <nml:Link id="␣urn:ogf:network:example.net:2012:linkA:XY"/>
  </nml:Relation>
</nml:Port>

<nml:Port id="urn:ogf:network:example.net:2012:port_Y:in">
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#isSink">
    <nml:Link id="urn:ogf:network:example.net:2012:linkA:XY"/>
  </nml:Relation>
</nml:Port>
```

  - *UnidirectionalLink that is composed of more than one sub-link*

```
<nml:Link id="urn:ogf:network:example.net:2012:link_XW">
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#isSerialCompoundLink">
    <nml:Link id="urn:ogf:network:example.net:2012:linkA:XY">
      <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#next">
        <nml:Link id="urn:ogf:network:example.net:2012:linkB:YZ"/>
      </nml:Relation>
    </nml:Link>
    <nml:Link id="urn:ogf:network:example.net:2012:linkB:YZ">
      <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#next">
        <nml:Link id="urn:ogf:network:example.net:2012:linkC:ZW"/>
      </nml:Relation>
    </nml:Link>
    <nml:Link id="urn:ogf:network:example.net:2012:linkC:ZW"/>
  </nml:Relation>
</nml:Link>
```

  - *BidirectionalLink* (section 2.1.14)

```
<nml:BidirectionalLink id="urn:ogf:network:example.net:2012:link_XWX">
  <nml:name>Link between ports X and W</nml:name>
  <nml:Link id="urn:ogf:network:example.net:2012:link_XW"/>
  <nml:Link id="urn:ogf:network:example.net:2012:link_WX"/>
</nml:BidirectionalLink>
```

- *LinkGroup* (section 2.1.12)

```
<nml:LinkGroup id="urn:ogf:network:example.net:2012:domainy_domainx">
  <nml:LabelGroup labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">
    1780−1783
  </nml:LabelGroup>
</nml:LinkGroup>
```

- *Labels*
  - *Label* (section 2.1.17)

```
<nml:Label labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">1501</nml:Label>
```

  - *LabelGroup* (section 2.1.18)

```
<nml:LabelGroup labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">
  1780−1783
</nml:LabelGroup>
```

- *Location* (section 2.1.15)

```
<nml:Location id="urn:ogf:network:example.net:2012:redcity">
  <nml:name>Red City</nml:name>
  <nml:lat>30.600</nml:lat>
  <nml:long>12.640</nml:long>
</nml:Location>
```

- *Services*
  - *SwitchingService* (section 2.1.6)

```
<nml:Node id="urn:ogf:network:example.net:2012:nodeA">
  <nml:name>Node_A</nml:name>
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#hasInboundPort">
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_X:in" />
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_Y:in" />
  </nml:Relation>
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#hasOutboundPort">
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_X:out"/>
    <nml:Port id="urn:ogf:network:example.net:2012:nodeA:port_Y:out"/>
  </nml:Relation>
  <nml:Relation type="http://schemas.ogf.org/nml/2013/03/base#hasService">
    <nml:SwitchingService id="urn:ogf:network:example.net:2012:nodeA:switchingService"/>

5.2 Examples in OWL

The following snippets represent NML structures in the OWL format. The namespaces used in all the examples follow the definitions of the Topology example.

- *Topology* (section 2.1.10)

```
<?xml version="1.0" encoding="utf-8"?>
<rdf:RDF
  xmlns:nml="http://schemas.ogf.org/nml/2013/03/base#"
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:owl="http://www.w3.org/2002/07/owl#"
  xmlns:nmleth="http://schemas.ogf.org/nml/2013/03/ethernet#"
>
<nml:Topology rdf:about="urn:ogf:network:example.net:2012:org">
    <nml:version>20120814</nml:version>

  <!-- ... -->

</nml:Topology>
```

- *Node* (section 2.1.2)

```
<nml:Node rdf:about="urn:ogf:network:example.net:2012:nodeA">
  <nml:name>Node_A</nml:name>
  <nml:locatedAt rdf:resource="urn:ogf:network:example.net:2012:redcity"/>
  <nml:hasOutboundPort rdf:resource="urn:ogf:network:example.net:2012:nodeA:port_X:out"/>
  <nml:hasOutboundPort rdf:resource="urn:ogf:network:example.net:2012:nodeA:port_Y:out"/>
  <nml:hasInboundPort rdf:resource="urn:ogf:network:example.net:2012:nodeA:port_X:in"/>
  <nml:hasInboundPort rdf:resource="urn:ogf:network:example.net:2012:nodeA:port_Y:in"/>
</nml:Node>
```

- *Ports*
  - *UnidirectionalPort* (section 2.1.3)

```

<nml:Port rdf:about="urn:ogf:network:example.net:2012:port_X:out">
    <nmleth:vlan>1501</nmleth:vlan>
</nml:Port>
```

  - *BidirectionalPort* (section 2.1.13)

```
<nml:BidirectionalPort rdf:about="urn:ogf:network:example.net:2012:port_X">
  <nml:name>X</nml:name>
  <nml:hasPort rdf:resource="urn:ogf:network:example.net:2012:port_X:out"/>
  <nml:hasPort rdf:resource="urn:ogf:network:example.net:2012:port_X:in"/>
</nml:BidirectionalPort>
```

- *PortGroup* (section 2.1.11)

```
<nml:PortGroup rdf:about="urn:ogf:network:example.net:2012:portgroup_X:out">
    <nml:hasLabel>
      <nml:LabelGroup labeltype="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">
        1780−1783
      </nml:LabelGroup>
    </nml:hasLabel>
</nml:PortGroup>
```

- *Links*
  - *UnidirectionalLink* (section 2.1.4)

```
<nml:Link rdf:about="urn:ogf:network:example.net:2012:linkA:XY"/>

<nml:Port rdf:about="urn:ogf:network:example.net:2012:port_X:out">
  <nml:isSource rdf:resource="urn:ogf:network:example.net:2012:linkA:XY"/>
</nml:Port>

<nml:Port id="urn:ogf:network:example.net:2012:port_Y:in">
  <nml:isSink rdf:resource="urn:ogf:network:example.net:2012:linkA:XY"/>
</nml:Port>
```

  - *UnidirectionalLink that is composed of more than one sub-link*

```
<nml:Link rdf:about="urn:ogf:network:example.net:2012:link_XW">
  <nml:isSerialCompoundLink>
    <nml:ListItem rdf:resource="urn:ogf:network:example.net:2012:link_XW_1">
      <nml:item rdf:resource="urn:ogf:network:example.net:2012:linkA:XY"/>
      <nml:next rdf:resource="urn:ogf:network:example.net:2012:link_XW_2"/>
    </nml:ListItem>
  </nml:isSerialCompoundLink>
</nml:Link>

<nml:ListItem rdf:resource="urn:ogf:network:example.net:2012:link_XW_2">
  <nml:item rdf:resource="urn:ogf:network:example.net:2012:linkB:YZ"/>
  <nml:next rdf:resource="urn:ogf:network:example.net:2012:link_XW_3"/>
</nml:ListItem>

<nml:ListItem rdf:resource="urn:ogf:network:example.net:2012:link_XW_3">
  <nml:item rdf:resource="urn:ogf:network:example.net:2012:linkC:ZW"/>
</nml:ListItem>
```

  - *BidirectionalLink* (section 2.1.14)

```
<nml:BidirectionalLink rdf:about="urn:ogf:network:example.net:2012:link_XWX">
  <nml:name>Link between ports X and W</nml:name>
  <nml:hasLink rdf:about="urn:ogf:network:example.net:2012:link_XW"/>
  <nml:hasLink rdf:about="urn:ogf:network:example.net:2012:link_WX"/>
</nml:BidirectionalLink>
```

- *LinkGroup* (section 2.1.12)

```
<nml:LinkGroup rdf:about="urn:ogf:network:example.net:2012:domainy_domainx">
  <nmleth:vlan>1780−1783</nmleth:vlan>
</nml:LinkGroup>
```

- *Labels*
  - *Label* (section 2.1.17)

```
<rdf:Description rdf:about="http://schemas.ogf.org/nml/2013/03/ethernet#vlan">
  <owl:subPropertyOf rdf:resource="http://schemas.ogf.org/nml/2013/03/base#hasLabel"/>
</rdf:Description>

    </nml:DeadaptationService>
  </nml:hasService>
</nml:Port>
```

6 Security Considerations

There are important security concerns associated with the generation and distribution of network topology information. For example, ISPs frequently consider network topologies to be proprietary. We do not address these concerns in this document, but implementers are encouraged to consider the security implications of generating and distributing network topology information.

Implementers should be aware that the NML descriptions do not provide any guarantee regarding their integrity nor their authenticity. The NML documents also can not provide this for the identifiers contained in the documents. Implementers should use external means of verifying the authenticity of identifiers contained in the documents.
