# 1 Introduction

This document describes the base schema of the Network Markup Language (NML). Section 2.1 defines the NML classes and their attributes and parameters. Section 2.2 describes the relations defined between NML classes.

A NML network description can be expressed in XML, RDF/XML and Turtle syntax. Section 4 describes the RNC and XSD schema for the XML syntax. Section 5 describes the OWL 2 schema for the XML/RDF and Turtle syntaxes.

These basic classes defined in this document may be extended, or sub-classed, to represent technology specific classes.

Section 6 provides example use cases. This section is informative. Only sections 2 thru 5 are normative and considered part of the recommendation.

### 1.1 Scope

The Network Markup Language is designed to create a functional description of multi-layer networks (including virtualised networks) and multi-domain networks (including aggregated or abstracted networks). It can not only describe a statics network topology, but also its capabilities and its configuration.

NML is aimed at logical connection-oriented network topologies. It can also be used to describe physical networks or packet-oriented networks, although the current base schema current version does not contain classes or properties to explicitly deal with signal degradation, or complex routing tables.

NML only attempts to describe the data plane of a computer network, not the control plane. It does contain extension mechanism to easily tie it with network provisioning standards and with network monitoring standards.

Finally, you will not find a definition for the terms *Network* or *capacity* in this document. This has been a conscious choice. The term *Network* has become so widely used for so many diverse meanings that it is impossible to create a definition that everyone can agree on, while still expressing something useful. See *Topology* for the concept of a network domain and a *Link* with multiple sources and sinks for the concept of a local area network. The term *capacity* is used by different technologies in such a different way (e.g. including or excluding the packet overhead) that it is better to let technology-specific extensions make an explicit definition.

# 1.2 Notational Conventions

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD", "SHOULD", "MAY", and "OPTIONAL" are to be interpreted as described in [RFC 2119].

This schema defines classes, attributes, relations, parameters and logic. Objects are instances of classes, and the type of an object is a class.

Names of classes are capitalised and written in italics (e.g. the *Node* class). Names of relations are written in camel case and in italics (e.g. the *hasNode* relations).

# 2 NML Base Schema

The NML Base schema describes an information model for computer networks. This schema is kept intentionally general, with provisions to extend the schema to describe layer-specific information.

The schema consists of classes, attributes, relations, parameters and logic. Classes describe types of objects and are described in section 2.1. Relations describe the relations between classes and are described in section 2.2. Attributes describe properties of classes. Logic describes how some relations may be derived from other relations. Parameters, like attributes, are properties of classes, but may (subtly) change the logic. Logic is described in section 2.3. Attributes and parameters are described with their class description.

All classes, relations, attributes and parameters defined in this document have an identifier within the namespace http://schemas.ogf.org/nml/2012/10/base#.

Figure 1: A UML class diagram of the classes in the NML schema and their hierarchy

#### 2.1 Classes

Figure 1 shows an overview of all the classes in the NML schema in a UML class diagram. In the sections below we discuss each of the elements of the schema.

#### 2.1.1 Network Object

The basic abstract class of the schema is the *Network Object*. Most classes inherit from it.

Network Object is an abstract class. It must not be instantiated directly.

A Network Object may have the following relations:

- existsDuring to one or more Lifetimes
- isAlias to one or more Network Objects
- locatedAt to one Location

A Network Object may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string
- version to assign a time stamp

A Network Object may have the following parameter:

• isReference A value of false means that the description of the Network Object is authoritative and complete. A value of true means that the Network Object is defined elsewhere and is only augmented in the current topology description. The default value is false.

The meaning of the *isAlias* relation is only defined for specific cases (between objects of the same class), and MUST NOT be used between other objects.

The meaning of the *version* attribute is only defined for specific cases (in objects of the Topology class), and SHOULD NOT be used in other objects. Clients that receive a *version* attribute for a non-*Topology* object MAY ignore that attribute.

An *id* is a persistent, globally unique object identifier for the *Network Object*. Section 3 describes these identifiers in detail.

name is a human readable string. A name may be written in any language, but it is REC-OMMENDED that names are chosen so that all users can easily distinguish between different names. Two objects MAY have the same name. It is RECOMMENDED to use short, descriptive

names. A name MUST NOT be used for anything other than display purposes. Normal Unicode recommendations apply: A name MUST NOT contain control or formatting codepoint (anything in the Other categories), and it is RECOMMENDED to only use codepoints from the Basic Multilingual Plane (BMP).

version is a time stamp in ISO 8601 format. The time stamp can be used to publish updates of a *Topology*. If a client receives multiple *Topology* descriptions, each with a different version time stamp, the version with the latest time stamp in the past or present MUST be considered the valid description. *Topology* descriptions with a time stamp in the future MAY be discarded or cached until the denoted time. See also the *Lifetime* object to describe historic or future network changes.

The base *Network Object* is subclassed into the top-level topology components, that are sufficient to cover the description of networks. The classes in this schema that directly inherit from *Network Object* are:

- Node
- Port
- Link
- Service
- Group

These classes are described in more detail below.

#### 2.1.2 Node

A *Node* is generally a device connected to, or part of, the network. A Node does not necessarily correspond to a physical machine. It MAY be a virtual device or a group of devices.

Node inherits from Network Object.

A *Node* may have the following relations:

- existsDuring to one or more Lifetimes
- hasInboundPort to one or more Ports or PortGroups
- hasOutboundPort to one or more Ports or PortGroups
- hasService to one or more Services of type Switch
- *implementedBy* to one or more *Nodes*

- *isAlias* to one or more *Nodes*
- locatedAt to one Location

A *Node* may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string

A *Node* may have the following parameter:

• *isReference* to describe if the *Node* is defined elsewhere.

#### 2.1.3 Port

A Port defines connectivity from a Network Object to the rest of the network. A Port object is unidirectional. A Port does not necessarily correspond to a physical interface. It represents a logical transport entity at a fixed place in the network.

Port inherits from Network Object.

A *Port* may have the following relations:

- existsDuring to one or more Lifetimes
- hasLabel to one Label
- hasService to one or more Services of type Adaptation or type Deadaptation
- isAlias to one or more Ports
- isSink to one or more Links
- *isSource* to one or more *Links*

A *Port* may have the following attributes:

- encoding to assign a data encoding identifier
- id to assign a persistent globally unique URI
- name to assign a human readable string

A *Port* may have the following parameter:

• *isReference* to describe if the *Port* is defined elsewhere.

#### 2.1.4 Link

A *Link* object describes a unidirectional data transport from each of its sources to all of its sinks.

A source of a Link is a Network Object that has a *isSource* relation to the Link. A sink of a Link is a Network Object that has a *isSink* relation to the Link.

Link inherits from Network Object.

A *Link* may have the following relations:

- existsDuring to one or more Lifetimes
- hasLabel to one Label
- isAlias to one or more Links
- isSerialCompoundLink to one ordered List of Links

A *Link* may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string

A *Link* may have the following parameters:

- isReference to describe if the Link is defined elsewhere.
- noReturnTraffic. A value of true changes the definition of Link to: data transport from each sources to all sinks, except that there is no data transport from a source to a sink if the source and sink are grouped together in a BidirectionalPort group. The default value of noReturnTraffic is false.

#### 2.1.5 Service

Service describes a capability of the network. That is, it describes how a configuration can be changed dynamically.

Service is an abstract class. It MUST NOT be instantiated directly.

Service inherits from Network Object. A Service may have the same relations, attributes and parameters as a Network Object.

This schema defines three different services, the *SwitchingService* the *AdaptationService* and the *DeadaptationService*. These are described in more detail below.

#### 2.1.6 Switching Service

A SwitchingService describes the ability to create cross connects from its inbound Ports to its outbound Ports.

SwitchingService inherits from Service.

A SwitchingService may have the following relations:

- existsDuring to one or more Lifetimes
- hasInboundPort to one or more Ports or PortGroups
- hasOutboundPort to one or more Ports or PortGroups
- isAlias to one or more Switching Services
- providesLink to one or more Links or LinkGroups.

A SwitchingService may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string

A SwitchingService may have the following parameters:

- isReference to describe if the SwitchingService is defined elsewhere.
- labelSwapping. A value of false adds a restriction to the SwitchingService: it is only able to create cross connects from an inbound Port to an outbound Port if the Label of the connected Ports has the same value. The default value is false.

The *providesLink* relation points to *Links* which describe the currently configured cross connects in a *SwitchingService*.

#### 2.1.7 Adaptation Service

An AdaptationService describes the capability that data from one or more Ports can be embedded in the data encoding of one other Port. This is commonly referred to as the embedding of client layer (higher network layer) ports in a server layer (lower network layer) port. The AdaptationService describes a multiplexing adaptation function, meaning that different channels (the client layer ports) can be embedded in a single data stream (the server layer port).

Like *Port* and *Link*, *AdaptationService* describes a unidirectional transport function. For the inverse transport function, see *DeadaptationService*.

An AdaptationServices describe

AdaptationService inherits from Service.

An AdaptationService may have the following relations:

- existsDuring to one or more Lifetimes
- isAlias to one or more AdaptationServices
- providesPort to one or more Ports or PortGroups

An AdaptationService may have the following attributes:

- adaptation to assign an adaptation technology identifier
- id to assign a persistent globally unique URI
- name to assign a human readable string

A AdaptationService may have the following parameter:

• is Reference to describe if the Adaptation Service is defined elsewhere.

#### 2.1.8 De-adaptation Service

A DeadaptationService describes the capability that data of one or more ports can be extracted from the data encoding of one other port. This is commonly referred to as the extraction of client layer (higher network layer) ports from the server layer (lower network layer) port. The DeadaptationService describes a multiplexing adaptation function, meaning that different channels (the client layer ports) can be extracted from a single data stream (the server layer port).

Like Port and Link, AdaptationService describes a unidirectional transport function. For the inverse transport function, see  $AdaptationService^{1}$ .

DeadaptationService inherits from Service.

A DeadaptationService may have the following relations:

- existsDuring to one or more Lifetimes
- isAlias to one or more DeadaptationServices

<sup>&</sup>lt;sup>1</sup>Whilst the *DeadaptationService* is an inverse of te *AdaptationService*, it should not be confused with an inverse multiplexing adaptation function. An inverse multiplexing adaptation function embeds a single data stream in multiple underlying data streams. To describes such a network, the experimental *parallelCompound* relation can be used, which is described in a seperate document [Dijkstra13].

• providesPort to one or more Ports or PortGroups

A DeadaptationService may have the following attributes:

- adaptation to assign a adaptation technology identifier
- *id* to assign a persistent globally unique URI
- name to assign a human readable string

A DeadaptationService may have the following parameter:

• is Reference to describe if the Deadaptation Service is defined elsewhere.

#### 2.1.9 Group

A *Group* describes a collections of network objects. Any object can be part of a group, including another *Group*.

*Group* is an abstract class. It MUST NOT be instantiated directly.

*Group* inherits from *Network Object*. A *Group* may have the same relations, attributes and parameters as a *Network Object*.

This schema defines five different *Groups*:

- Topology
- Port Group
- Link Group
- Bidirectional Port
- Bidirectional Link

These classes are described in more detail below.

### 2.1.10 Topology

A Topology<sup>2</sup> is a set of connected Network Objects. connected means that there is, or it is possible to create, a data transport between any two Network Objects in the same Topology, provided that there are no policy, availability or technical restrictions.

A *Topology* may have the following relations:

 $<sup>^2</sup>$ At first this was called a Network, then Graph Network. The term Topology was suggested to avoid the confusion surrounding the term Network.

- existsDuring to one or more Lifetimes
- hasNode to one or more Nodes
- hasInboundPort to one or more Ports or PortGroups
- hasOutboundPort to one or more Ports or PortGroups
- hasService to one or more Service of type Switch
- has Topology to one or more Topologys
- *isAlias* to one or more *Topologys*
- locatedAt to one Location

A *Topology* may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string
- version to assign a serial number

A *Topology* may have the following parameter:

• *isReference* to describe if the *Topology* is defined elsewhere.

The version attribute is described at the Network Object.

#### 2.1.11 Port Group

A *PortGroup* is an unordered set of *Ports*.

A *PortGroup* may have the following relations:

- existsDuring to one or more Lifetimes
- hasLabelGroup to one LabelGroup
- hasPort to one or more Ports or PortGroups
- *isAlias* to one or more *PortGroups*
- *isSink* to one or more *LinkGroups*
- *isSource* to one or more *LinkGroups*

A PortGroup may have the following attributes:

• encoding to assign a data encoding identifier

- id to assign a persistent globally unique URI
- name to assign a human readable string

A *PortGroup* may have the following parameter:

• isReference to describe if the PortGroup is defined elsewhere.

#### 2.1.12 Link Group

A LinkGroup is an unordered set of Links.

A *LinkGroup* may have the following relations:

- existsDuring to one or more Lifetimes
- hasLabelGroup to one LabelGroup
- hasLink to one or more Links or LinkGroups
- isAlias to one or more LinkGroups
- isSerialCompoundLink to one ordered List of LinkGroups

A LinkGroup may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string

A LinkGroup may have the following parameter:

• isReference to describe if the LinkGroup is defined elsewhere.

#### 2.1.13 Bidirectional Port

A BidirectionalPort is a group of two (unidirectional) Ports or PortGroups together forming a bidirectional representation of a physical or virtual port.

A BidirectionalPort may have the following relations:

- existsDuring to one or more Lifetimes
- hasPort to exactly two Ports or two PortGroups

A BidirectionalPort may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string

A BidirectionalPort may have the following parameter:

• isReference to describe if the BidirectionalPort is defined elsewhere.

#### 2.1.14 Bidirectional Link

A BidirectionalLink is a group of two (unidirectional) Links or LinkGroups together forming a bidirectional link.

A BidirectionalLink may have the following relations:

- existsDuring to one or more Lifetimes
- hasLink to exactly two Links or two LinkGroups

A BidirectionalLink may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string

A BidirectionalLink may have the following parameter:

• isReference to describe if the BidirectionalLink is defined elsewhere.

#### 2.1.15 Location

A Location is a reference to a geographical location or area.

A *Location* may have the following attributes:

- id to assign a persistent globally unique URI
- name to assign a human readable string
- long is the longitude in WGS84 coordinate system (in decimal degrees)
- lat is the lattitude in WGS84 coordinate system (in decimal degrees)
- alt is the altitude in WGS84 coordinate system (in decimal meters)
- unlocode is the UN/LOCODE location identifier
- address is a vCard address

A *Location* may have the following parameter:

• isReference to describe if the Location is defined elsewhere.

#### 2.1.16 Lifetime

A Lifetime is an interval between which the object is said to be active.

A *Lifetime* may have the following attributes:

- start is the start time and date in ISO datetime notation
- end is the end time and date in ISO datetime notation

#### 2.1.17 Ordered List

An OrderedList is an ordered list of Network Objects.

The representation of an *OrderedList* depends on the syntax.

#### 2.1.18 Label

A *Label* is the technology-specific value to distinguish a single data stream embedded in a larger data stream. The *value* can either be a resource label, or a pair of source and destination labels.

A *Label* may have the following attributes:

- type to refer to a technology-specific labelset
- value is one specific value taken from the labelset

Technology extensions of NML may define additional attributes.

#### 2.1.19 Label Group

A LabelGroup is an unordered set of Labels.

A LabelGroup may have the following attributes:

- type to refer to a technology-specific labelset
- values is a set of specific values taken from the labelset

Technology extensions of NML may define additional attributes.

#### 2.2 Relations

Relations describe how different Network Objects can be combined to form a network topology description. The relations have been described above, but for ease of reference we also give

a full list and definition here (in alphabetical order). In principle a *Relation* can go from any object to any other object. The list below includes definitions for a subset of the possible relations. If a particular *Relation* between two *Network Objects* is not listed below, it is undefined.

existsDuring relates a LifeTime object to a Network Object

hasInboundPort defines the relation between a Node, a SwitchingService or a Topology and their respective Ports or PortGroups

hasLabelGroup assigns one LabelGroup to a PortGroup

hasLabel assigns one Label to a Port

**hasLink** is used for:

- Bidirectional Link to relate exactly two Links or two LinkGroups
- LinkGroup to one or more Links or LinkGroups to define membership of that group

hasNode relates a Network Object to a Node, meaning that a Node is part of a Topology

hasOutboundPort relates either a Node, SwitchingService or a Topology to one or more Ports or PortGroups as an outbound port

**hasPort** is used for:

- BidirectionalPort to relate exactly two Ports or two PortGroups
- PortGroup to one or more Ports or PortGroups

hasService relates a *Network Object* to a *Service*. This schema only defines the meaning of:

- Port to AdaptationService, relating one server-layer Port to an adaptation function
- Port to DeadaptationService, relating one server-layer Port to a deadaptation function
- Node or Topology to SwitchingService, describing a switching capability of that Node or Topology.

hasSink relates a Link to one Port to define the outgoing traffic port

hasSource relates a Link to one Port to define its incoming traffic port

hasTopology defines a relation between one *Topology* to one or more *Topology*s for aggregation purposes

- **implementedBy** relates a *Node* to one or more *Nodes* to describe virtualization
- **isAlias** is a relation from a *Network Object* to a *Network Object* to describe that one can be used as the alias of another.
- isSerialCompoundLink is used to define that a Link or LinkGroup represents an ordered List of Links or LinkGroups. This must include cross-connects.
- **locatedAt** relates a Network Object to one Location
- **providesLink** is used to relate a *SwitchingService* to one or more *Links* or *LinkGroups* to define that these have been created by that *SwitchingService*
- **providesPort** is used to relate an *AdaptationService* or *DeadaptationService* to one or more *Ports* or *PortGroups* to define that these have been created by that *AdaptationService* or *DeadaptationService* 
  - The hasTopology, hasNode, implementedBy hasPort, hasLabel, hasLabelGroup, and hasLink are defined as implicit relations.

# 2.3 Logic

# 3 Identifiers

## 3.1 Object Identifiers

The namespace for the class objects defined in this document is http://schemas.ogf.org/nml/base/2013, TODO: change to correct year and month of the schema.

All objects and attributes defined in this document reside in this namespace. For example, the link object is identified by http://schemas.ogf.org/nml/2013/10/base/link

#### 3.2 Instance Identifiers

Section 2.1.1 requires that instances of Network Objects MUST have an *id* attribute, which MUST be a unique URI.

Implementations that receive a network topology description MUST be prepared to accept any valid URI as an identifier.

Implementations that publish a network topology description instance identifiers MAY adhere to the syntax of Global Network Identifiers as defined in [URN-OGF-NETWORK], which ensures global uniqueness and that easy recognition of Network Object instances.

Two different Network Objects instance MUST have two different identifiers.

Once an identifier is assigned to a resource, it MUST NOT be re-assigned to another resource.

A URI MAY be interpreted as an International Resource Identifier (IRI) for display purposes, but URIs from external source domains MUST NOT be IRI-normalised before transmitting to others.

#### 3.2.1 Lexical Equivalence

Two identifier are lexical equivalent if they are binary equivalent after case folding.

No interpretation of percent-encoding or PUNYCODE decoding should take place.

For the purpose of equivalence comparison, any possible fragment part or query part of the URI is considered part of the URI.

For example the following identifiers are equivalent:

```
1 - urn:ogf:network:example.net:2012:local_string_1234
2 - URN:OGF:network:EXAMPLE.NET:2012:Local_String_1234
```

while the following identifiers are not equivalent (in this case, the percentage encoding even make URI #3 an invalid Global Network Identifier.):

```
1 - urn:ogf:network:example.net:2012:local_string_1234
```

3 - urn:ogf:network:example.net:2012:local%5Fstring%5F1234

#### 3.2.2 Further Restrictions

An assigning organisation MUST NOT assign Network Object Identifier longer than 255 characters in length.

Parsers MUST be prepared to accept identifiers of up to 255 characters in length.

A Parser SHOULD verify if an identifier adheres to the general URI syntax rules, as specified in RFC 3986 [RFC 3986].

Parsers SHOULD reject identifiers which do not adhere to the specified rules. A parser encountering an invalid identifier SHOULD reply with an error code that includes the malformed identifier, but MAY accept the rest of the message, after purging all references to the Network Object with the malformed identifier.

## 3.2.3 Interpreting Identifiers

A Network Object identifier MUST be treated as a opaque string, only used to uniquely identify a Network Object. The local-part of a Global Network Identifier MAY have certain meaning to it's assigning organisation, but MUST NOT be interpreted by any other organisation.

#### 3.2.4 Network Object Attribute Change

A Network Object may change during its lifetime. If these changes are so drastic that the assigning organisation considers it a completely new Network Object, the assigning organisation should be assigned a new identifier. In this case, other organisations MUST treat this object as completely new Network Resource.

If the assigning organisation considers the changes are small, it MUST retain the same identifier for the Network Object, and use some mechanism to signal it's peers of the changes in the attributes of the Network Object.

# 4 XML Schema

# 5 OWL Schema

# 6 Examples

The following snippets represent NML structures in the XML format.

• Topology

```
<nml:Topology xmlns:nml="http://schemas.ogf.org/nml/2012/10/nml"
    id="urn:ogf:network:example.net:2012:org"
        version="20120814">
    <!-- ... -->
    </nml:Topology>
```

• Node

```
<nml:Node id="urn:ogf:network:example.net:2012:nodeA">
  <nml:name>Node_A</nml:name>
  <nml:Location idRef="urn:ogf:network:example.net:2012:redcity"/>
  <nml:Relation type="http://schemas.ogf.org/nml/2012/10/relation/hasOutboundPort">
  <nml:Port idRef="urn:ogf:network:example.net:2012:nodeA:port_X:out"/>
  <nml:Port idRef="urn:ogf:network:example.net:2012:nodeA:port_Y:out"/>
  <nml:Relation>
  <nml:Relation>
  <nml:Relation type="http://schemas.ogf.org/nml/2012/10/relation/hasInboundPort">
  <nml:Port idRef="urn:ogf:network:example.net:2012:nodeA:port_X:in"/>
  <nml:Port idRef="urn:ogf:network:example.net:2012:nodeA:port_X:in"/>
  <nml:Port idRef="urn:ogf:network:example.net:2012:nodeA:port_Y:in"/>
  </nml:Relation>
  </nml:Node>
```

#### • Ports

- Unidirectional Port

- BidirectionalPort

```
<nml:BidirectionalPort id="urn:ogf:network:example.net:2012:port_X">
  <nml:name>X</nml:name>
  <nml:Port idRef="urn:ogf:network:example.net:2012:port_X:out"/>
  <nml:Port idRef="urn:ogf:network:example.net:2012:port_X:in"/>
  <nml:BidirectionalPort>
```

- PortGroup

• Link

#### - UnidirectionalLink

- UnidirectionalLink that is composed of more than one sub-link

- BidirectionalLink

- LinkGroup

#### • Labels

- Label

```
<\!\!\mathbf{nml:Label} \ \ \mathsf{encoding} = \texttt{"http://schemas.ogf.org/nml/2012/10/ethernet/vlan"} > 1501 <\!\!/\mathbf{nml:Label} > 1500 <\!\!/\mathbf
```

 $- \ Label Group$ 

```
<\! nml:LabelGroup <code>encoding="http://schemas.ogf.org/nml/2012/10/ethernet/vlan">1780-1783<br/> </nml:LabelGroup></code>
```

#### • Location

```

# 7 Security Considerations

There are important security concerns associated with the generation and distribution of network topology information. For example, ISPs frequently consider network topologies to be proprietary. We do not address these concerns in this document, but implementers are encouraged to consider the security implications of generating and distributing network topology information.
